[12]:
```python
# Step 1: Wages with f-strings

name = "Ehmar"
hourly_wage = 920.0
hours = 32
weekly_pay = hourly_wage * hours
print(f"{name} earns ${weekly_pay} per week.")
```

```
Ehmar earns $29440.0 per week.
```

[11]:
```python
# Step 2: Count the warm days

temps = [61, 65, 72, 58, 70, 74, 68]
count = 0
for temp in temps:
    if temp > 65:
        count += 1
print(count)
```

```
4
```

[13]:
```python
# Step 3: Write a temperature converter

def to_celsius(f):
    return round((f - 32) * 5/9, 1)

print(to_celsius(temps[0]))
```

```
16.1
```

[ ]:
```python
# Step 4: A movie dictionary

movie_dict = {
    "title": "Whalefall",
    "year": 2026,
    "rating": 6.6
}

for key, value in movie_dict.items():
```

```
    print(f"{key}: {value}")
```

```
title: Whalefall
year: 2026
rating: 6.6
```

[ ]:
```
# Step 5: Load and inspect chickwts.csv

import pandas as pd
df = pd.read_csv("chickwts.csv")
display(df.head())
display(df.shape)
display(df.describe())
```

	Unnamed: 0	weight	feed
0	1	179	horsebean
1	2	160	horsebean
2	3	136	horsebean
3	4	227	horsebean
4	5	217	horsebean

(71, 3)

	Unnamed: 0	weight
count	71.000000	71.000000
mean	36.000000	261.309859
std	20.639767	78.073700
min	1.000000	108.000000
25%	18.500000	204.500000
50%	36.000000	258.000000
75%	53.500000	323.500000
max	71.000000	423.000000

Step 6: Interpret describe()

okay well at first it kind of threw me off, but after a staring and reading I think I pretty much got it -

Count: how many entries (rows) there are mean: mean of all the values in the numerical columns ("unnamed" and "weight") std: standard deviation form the standard formula im assuming min: minimum value 25%, 50%, and 75%: values of the curve generated from the population (i don't remember the right terminology from statistics…) max: maximum value

it's interesting because it finds all the columns with numerical values, so I guess this is where "data cleanup" is necessary
